ABSTRACT

It is well known that resveratrol (RSV) displayed cancer-preventing and anticancer properties but its clinical application is limited because of a low bioavailability and a rapid clearance from the circulation. Aim of this work was to synthesize pharmacologically active resveratrol analogs with an enhanced structural rigidity and bioavailability. In particular, we have synthesized a library of 2,3-thiazolidin-4-one derivatives in which a thiazolidinone nucleus connects two aromatic rings. Some of these compounds showed strong inhibitory effects on breast cancer cell growth. Our results indicate that some of thiazolidin-based resveratrol derivatives may become a new potent alternative tool for the treatment of human breast cancer.

Epidemiological and current laboratory studies suggest that consumption of certain types of fruits and vegetables, containing phytochemicals, is associated with reduced cancer risk. Furthermore, it is postulated that dietary phytochemicals can function as chemopreventive and/or adjuvant chemotherapeutic agents. One such phytochemical is resveratrol (3,5,4'-trihydroxy-trans-stilbene) (RSV), (Fig. 1) a naturally occurring phytoalexin, readily available in the diet and a lot of health-promoting effects have been ascribed to it.

Resveratrol, first identified as a bioactive compound in 1992, is found in several plants, particularly in the skin of red grapes. This compound has elicited much attention in recent years, as a potential anticancer agent, since its inhibitory effect on carcinogenic processes (initiation, promotion, and progression) was first reported in 1997. Thereafter extensive studies have verified the cancer-preventing and anticancer properties of resveratrol in various murine models of human cancer, including skin cancer (both chemically and ultraviolet B-induced), gastric and colorectal cancer, lung cancer, breast cancer, ovarian and prostate cancer, hepatoma, neuroblastoma, fibrosarcoma, pancreatic cancer, and leukemia. Several studies, using both in vitro and in vivo model systems, have illustrated resveratrol's capacity to modulate a multitude of signaling pathways associated with cellular growth and division, apoptosis, angiogenesis, invasion, and metastasis.

In particular, it exhibits an action in both hormone-sensitive and hormone-resistant breast cancer cells and shows cytostatic activity and determines cell growth arrest; these properties seem to be related to regulation of xenobiotic carcinogen metabolism and antiinflammatory, antiproliferative, and pro-apoptotic effects. The phytoestrogenic character of RSV was confirmed by its capacity to bind and activate α- and β-estrogen receptors (ERs) regulating transcription of estrogen-responsive target genes. However,
although a number of studies have been conducted, the effects of RSV on ERs remain controversial. For example, with MCF-7 cells in culture, Gehm et al.\(^7\) showed that RSV (3–10 \(\mu\)M) is a superagonist when combined with estradiol (E2), while Lu and Serrero\(^8\) reported ER antagonism of RSV (5 \(\mu\)M) in the presence of E2 and partial agonism in its absence.\(^8\) Bowers et al.\(^9\) observed partial to full agonism in CHO-K1 cells transfected with ER\(_{\alpha}\) or ER\(_{\beta}\) and reporter genes based on various estrogen receptor element (EREs). The authors showed that RSV (100 \(\mu\)M) acts as a mixed agonist/antagonist in cells transiently transfected with ER and mediates higher transcriptional activity when bound to ER\(_{\beta}\) than to ER\(_{\alpha}\). Moreover, RSV showed antagonist activity with ER\(_{\alpha}\), but not with ER\(_{\beta}\).\(^9\) Based on these reports, it appears that the ability of RSV to act as an ER agonist varies between different cell types and dosage.

Resveratrol acts as an estrogen-agonist or antagonist that depends

(continued on next page)
upon the relative abundance of ER-α and -β and the cis-regulatory sequences they target. Furthermore, resveratrol was also shown to inhibit the proliferation of the estrogen-receptor negative human breast carcinoma cell line, MDA-MB-468, by inhibiting the levels of autocrine growth stimulators.

Although the anticancer effects of resveratrol have been demonstrated, its clinical application is limited because of a low bioavailability and a rapid clearance from the circulation. In fact, in humans, three metabolic pathways have been identified, that is, sulfate and glucuronic acid conjugation of the phenolic groups and hydrogenation of the aliphatic double bond, the latter likely produced by the intestinal microflora. Extremely rapid sulfate conjugation by the intestine/liver appears to be the rate-limiting step in resveratrol’s bioavailability. Virtually no unconjugated resveratrol was detected in urine or serum samples, which could have implications regarding the significance of in vitro studies that used only unconjugated resveratrol.

The structural alteration of the stilbene moiety of resveratrol has been found to be a promising strategy for generation of several synthetic analogs with improved pharmacokinetic parameters. Moreover, the structure-activity studies have shown that methoxy groups added to the trihydroxystilbene scaffold of resveratrol, significantly potentiated its cytotoxic activity. In view of the significant biological and anticancer potential of RSV, we considered its structure as lead compound for the design and synthesis of small molecules with structural rigidity, enhance bioavailability and antitumoral activity. Recently, Mayhoub et al. described a series of 2,3-thiadiazol analogs of resveratrol using a strategy by the replacement of the alkene linker between the two aromatic rings with a heterocyclic system. This approach keeps the geometry of these rings relatively unchanged and close to that of the cis stilbene template. Now, we prepared a library of 2,3-diaryl-1-thiazolidinone derivatives in which a thiazolidin-4-one nucleus connects two aromatic rings (Fig. 2).

This design results in an increase in the structural rigidity of the new analogs, fixing the cis-conformation of resveratrol. Modifications on both aryl moieties have been also considered in order to define which functional groups are critical for cell proliferation control. These variations could lead to new restricted conformation analogs of resveratrol with higher cytotoxic activity that this and, hence, higher ability to inhibit the growth of cancer cells in vitro.

The synthesis of designed compounds (3–14, Table 1) was carried out by condensation of anilines (1) and aldehydes (2) with thioglycolic acid in THF using N,N-dicyclohexylcarbodiimide (DCC) as a dehydrating agent (Scheme 1). This protocol, described by Srivastava et al. has the advantage of mild reaction conditions,

Scheme 1. Synthesis of 2,3-thiazolidin-4-one derivatives (3–14).
a very short reaction time (1 h) and product formation in high yields (47–93%).

We evaluated the effects on cell proliferation of these new derivatives against estrogen receptor positive (ER+) MCF-7 (Fig. 3) and estrogen receptor negative (ER-) SKBR3 (Fig. 4) human breast cancer cell line at different concentrations (0.1, 1, 10 μM) using the MTT assay.

Therefore, we treated for 72 h MCF-7 and SKBR3 cells with each compounds and also with RSV in order to compare the anticancer effects of the chemicals used to this well-known anticancer agent.

In MCF7 cells, 5–8 (Fig. 3a), 9–12 (Fig. 3b) determined a clear dose-response inhibitory effect on cell growth. Low doses of 4 (Fig. 3a) and 13 (Fig. 3b) elicited an inhibition while higher doses do not favor it. 14 (Fig. 3b) decreased cell viability only at 1 and 10 μM concentrations. As showed in Figure 3b, the compounds 9 and 10 are more active.

In fact, the most interesting results were obtained for 9 and 10 characterized by the presence of –OMe groups in R3 and R4 and of an chlorine atom on the aromatic ring bonded at C-2 position, of the thiazolidinone moiety, respectively, as evidenced by half-maximal inhibitory concentration (IC50) values (Table 2).

In particular, the thiazolidin-4-one derivative 9 showed the best pattern of dose-dependent inhibition among substance tested with an IC50 of 2.58 μM, value much more relevant respect to RSV (IC50 = 28.07 μM).

In SKBR3 cells, 3–8 (Fig. 4a) and 9–11 (Fig. 4b) did not change cell proliferative behavior while only 10 μM of 5, 8–11 decreased significantly cell viability. Among all tested compounds in SKBR3 cells particularly 12–14 (Fig. 4b) determined a significant inhibition starting from the lowest dose. As showed in Figure 4 the presence of a phenyl unsubstituted (12), a naphtyl (13) or a trimethoxy-phenyl groups (14) at C2 position of the thiazolidinonic core were important for the inhibitory activity as indicated by IC50 values (Table 3).

In particular, the derivative 14 showed the best pattern of dose-dependent inhibition among tested substances with an IC50 of

0.23 μM, a value much more relevant than the IC50 value of RSV (41.42 μM).

It is evident that the dose at which RSV shows antiproliferative effects on MCF7 and SKBR3 cells is relatively higher (>10 μM) (Tables 2 and 3) compared to that of the tested compounds.

In addition, a control experiment using 3T3 mouse embryonic fibroblast cells has been performed; no effects on cell viability were obtained using all thiazolidin-based resveratrol derivatives of 0.1 μM from to 10 μM after 72 h of treatment (data not shown), suggesting that these compounds have specific inhibitory effect on breast cancer cells.

Because of the widespread chemopreventive and chemotherapeutic applications of resveratrol, a strong demand exists to search for other pharmacologically active resveratrol analogs with enhanced potency and selectivity. The findings arising from the studies described in this work could open a possible approach to the therapeutic applications of resveratrol, a strong demand exists to search for other pharmacologically active resveratrol analogs with enhanced potency and selectivity. Further experiments are needed to clarify the molecular effects on MCF7 and SKBR3 cells is relatively higher (>10 μM) (Tables 2 and 3) compared to that of the tested compounds.

2-(4-Chlorophenyl)-3-p-tolythiazolidin-4-one (11). White solid. Yield 56%. Mp. 215–217 °C. 1H NMR (300 MHz, DMSO): δ 2.28 (s, 3H), 3.86 (d, J = 15.7 Hz, 1H), 4.01 (d, J = 15.7 Hz, 1H), 6.05 (s, 1H), 7.01–7.03 (d, J = 8.8 Hz, 2H), 7.09–7.12 (d, J = 8.6 Hz, 2H), 7.26–7.28 (m, 4H). 13C NMR (75 MHz, DMSO): δ 21.4, 33.8, 65.3, 126.0, 128.9, 129.4, 130.1, 134.9, 135.0, 137.7, 138.5, 171.2. ESI m/z calc for C_{16}H_{13}ClNO: 281.05; found 281.07.

13C NMR (75 MHz, DMSO): δ 21.3, 33.5, 56.1, 60.8, 73.2, 106.1, 116.1, 129.2, 133.4, 136.8, 137.6, 152.8, 171.2. ESI m/z calc for C_{16}H_{13}ClNO: 281.05; found 281.07.

2-(Naphthalen-1-yl)-3-p-tolythiazolidin-4-one (13). White solid. Yield 56%. Mp. 215–217 °C. 1H NMR (300 MHz, DMSO): δ 2.29 (s, 3H), 3.80 (s, 9H), 3.89 (d, J = 15.7 Hz, 1H), 4.01 (d, J = 15.7 Hz, 1H), 6.01 (s, 1H), 6.50 (s, 2H), 7.07–7.10 (m, 4H). 13C NMR (75 MHz, DMSO): δ 21.3, 33.5, 56.1, 60.8, 73.2, 106.1, 116.1, 129.2, 133.4, 136.8, 137.6, 152.8, 171.2. ESI m/z calc for C_{19}H_{17}ClNO: 325.09; found 325.12.

18. Cell culture and treatments. MCF-7 breast cancer cells (a ER positive breast cancer cells, provided by Dr. E. Surmacz, Sbarro Institute for Cancer Research and Molecular Medicine, Philadelphia, USA) were maintained as previously described.19 SKBR3 breast cancer cells (a ER negative breast cancer cells, obtained from American Type Culture Collection (ATCC), Manassas, VA, USA) were maintained in RPMI1640 without phenol red supplemented with 10% fetal bovine serum (FBS), 1% glutamine and 1% penicillin/streptomycin (Sigma-Aldrich, Milan, Italy) (complete medium). Cells were maintained at 37 °C in a humidified atmosphere of 95% air and 5% CO2.

Synchronization. The effect of the different doses of compounds on cell synchronization. The effect of the different doses of compounds on cell cycle was measured using [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide] (MTT) assay as previously described.20–22 Seventy two hours after treatments, fresh MTT (Sigma), re-suspended in PBS, was added to each well (final concentration 0.33 mg/ml). After 3 h incubation, cells were lysed with 1 ml of DMSO. Each experiment was performed in triplicate and the optical density was measured at 570 nm in a spectrophotometer.

Statistical analyses. All experiments were conducted at least three times and the results were from representative experiments. Data were expressed as mean values ± standard deviation (SD), and the statistical significance between control (basal) and treated samples was analyzed using the GraphPad Prism 5 software program. The unpaired Student’s t-test was used to compare two groups. P < 0.05 was considered statistically significant.
